Report No. CE 90-02

Sofia and Los Angeles, 1990

## PREFACE

The task of the development of the National System for Recording, Analysis and Prediction of Strong Earthquakes shaking in Bulgaria was based on decision No. 117 of the Bureau of the Ministry Council held on 27 Dec. 1977, after the earthquake which took place on 4 March 1977 and had epicenter in the region of Vrancea (Romania). The necessary equipment, mainly accelerographs, were purchased with the financial support from various government ministries, industry and national councils. At present, at 26 settled areas, 84 accelerographs have been installed and are operating. The establishment, development and maintenance of this National Strong Motion Recording System is carried out by the Central Laboratory of Seismic Mechanics and Seismic Engineering of the Bulgarian Academy of Sciences.

The existence of this National System makes it possible to obtain data on 1) strong earthquake shaking on the territory of Bulgaria and the neighboring countries, and 2) on the effect of this shaking on earth and other structural systems. The important conclusions, based on the analysis of these data, can be used directly in the design practice, and in the development of methods for design of seismically safe structures. The ultimate goal of this work is to reduce the material and human losses during strong earthquakes.

During the period 1981-1987, numerous earthquakes have been recorded, including the ones in the cities of Strazitsa and of Provadia. More precisely, about 60 three-component accelerograms have been registered, which made the data base of stronger earthquakes recorded in Bulgaria. All the records were processed and analyzed in the Central Laboratory of Seismic Mechanics and Seismic Engineering of the Bulgarian Academy of Sciences, considering most recent developments in the field in the USSR, USA, Japan, China and other countries.

The Central Laboratory of Seismic Mechanics and Seismic Engineering is proposing to organize this data into a formal catalogue, to be used in scientific research and in solving various practical problems, in our country and abroad. This catalogue will contain graphical presentation of corrected acceleration, velocity and displacement time histories. Fourier amplitude spectra and response amplitude spectra will be presented for damping

ratios 0, 2, 5, 10, and 20%. The present catalogue does not include some of the recorded components, because of the poor quality of the film copies.

The publishing of the catalogue should be considered as an important step in the efforts of our scientists and specialists in the field in their pursuit to reduce the seismic risk in Bulgaria and on the Balkan peninsula.

Sofia, March 1990.

Prof. Dr. D. Nenov

Director

Central Laboratory of Seismic Mechanics  
and Seismic Engineering

## INTRODUCTION

The national network for recording, analysis and estimation of strong ground motions in Bulgaria was completed at the end of 1982. To date, 84 accelerographs have been installed at 26 residential sites (Fig. 1). The distribution of the accelerographs is such that the zones with high seismicity are covered. The network consists mainly of SMA-1 accelerographs recording the motion on photographic film. Nine of the instruments have sensitivity 0.5g, and 59 have sensitivity of 1g. There are three SMA-2 accelerographs recording the motion on analog magnetic tape. The FBA-3 accelerometers (12 units), together with the seismic triggering systems, form the FBA-3 system that records on a magnetic tape. Other four FBA-3 accelerometers belong to the CRA-1 system, recording on photographic film.

Part of the accelerographs are installed in buildings. In the buildings with two instruments, one is installed in the basement and the other one on the roof or on the upper floors. In the buildings with one instrument, the instrument is installed either in the basement or at the ground level. Past experience indicated also need for local networks of instruments (in the surroundings of the cities of Strazhitsa and Provadia, for example).

This national network of accelerographs recorded about 60 three-component accelerograms during the last 5 years. This required organization of the resulting data base (Dokev et al, 1987). The gathering of this data base of accelerograms and of various parameters of strong earthquakes, required by the design practice, is in fact an ever lasting process. This process requires organization of the data in such a way that the user spends least time on deciding on the type of data he has to extract from the data base for his work.

It is noted that this report does not contain all the records of events that have happened up to the present. This is because of the time period required for digitization, processing and analysis of the new records. This time period is longer when there are poor quality records and unidentified records.

The operation of the procedure for processing and analysis of the accelerograms can be described by four basic phases:

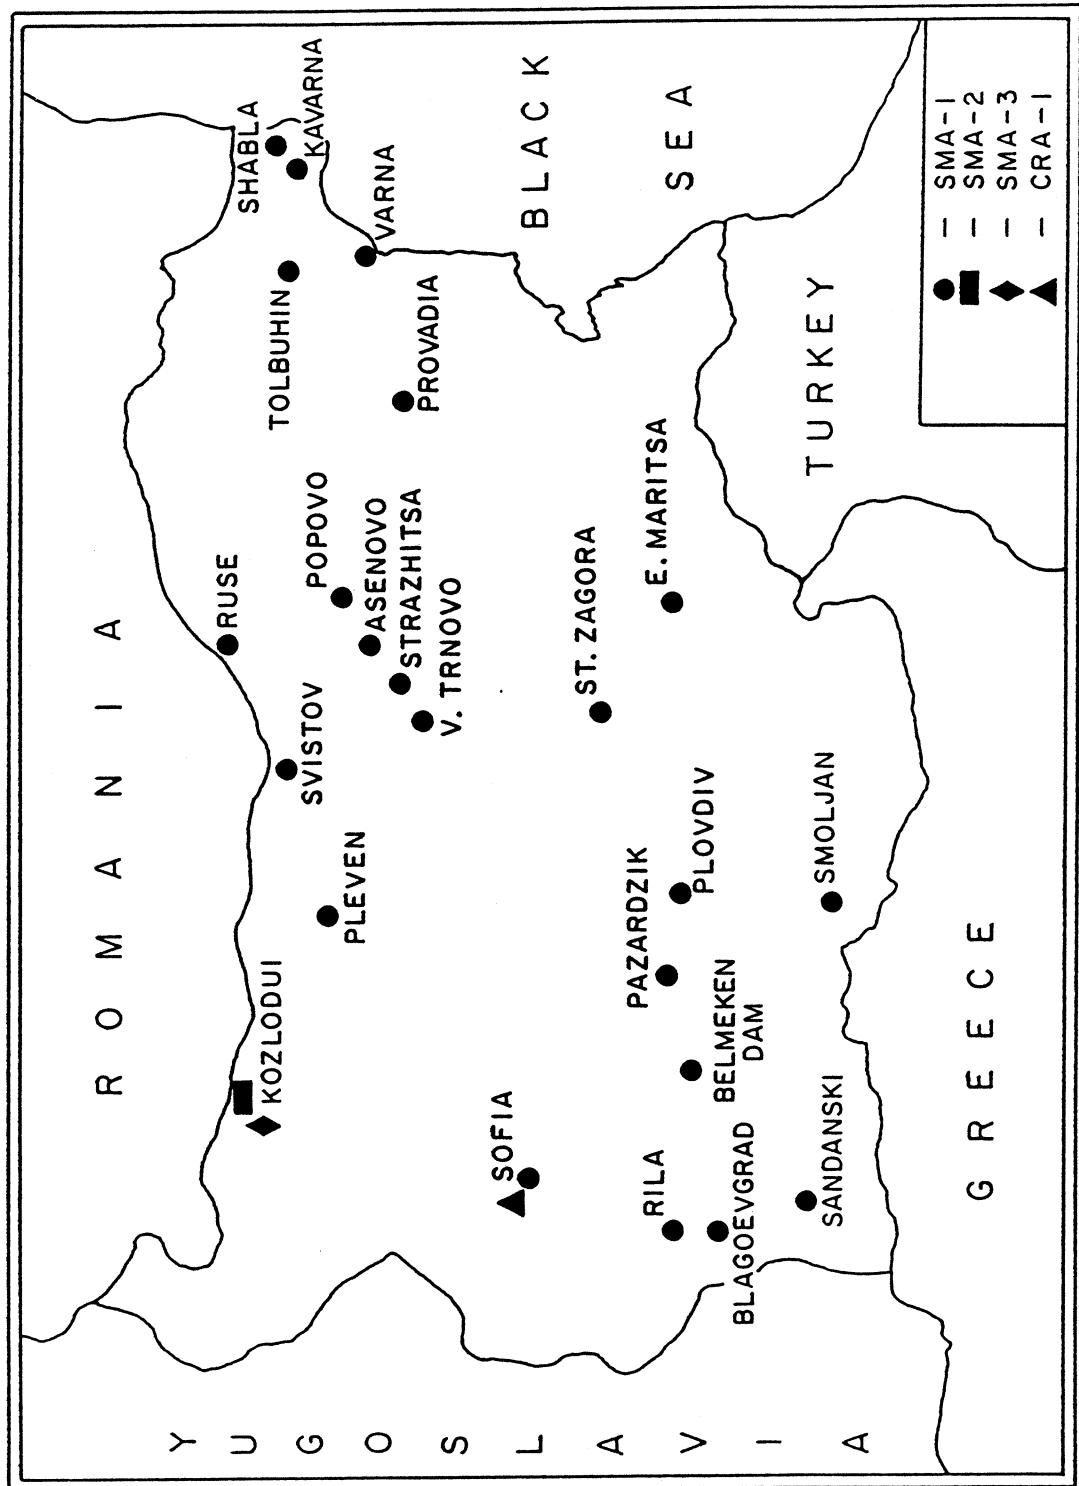

Figure 1 Geographical distribution of strong motion recording sites in Bulgaria.

- digitization and preparation of the uncorrected data;
- instrument correction and correction of errors in the uncorrected data;
- base line correction and calculation of velocity and displacement;
- calculation of Fourier and Response spectra,

For each phase, special investigations are performed so that the data is as close as possible to the actual seismic motion that took place, and according to the latest developments in the area of data processing.

The accelerograms included in this report have been recorded mostly in the basements of buildings or at ground level of one story houses. The latter ones can be considered as "free-field" records (Lee et al, 1982; Moslem and Trifunac, 1987).

From the available data, histograms have been prepared for the number of components of ground motion recorded. In Fig. 2 a histogram is shown representing the distribution of the recorded components of ground motion versus year, magnitude and intensity. In Fig. 3 the distributions of the recorded peak acceleration, velocity and displacement, are shown.

Table 1 represents a list of the earthquakes recorded by the national network of accelerographs. In the first column the sequential number of the earthquake is shown, in the second column - the date of the event (day, month, year) and in the third column - the time of the event (hour, minute, second and part of a second, using Greenwich Mean Time, GMT). In the next two columns are the coordinates of the epicenters (in degrees). The sixth column presents the depth of the focus (in kilometers). In the seventh and eight columns, the corresponding magnitude and epicentral intensity are given. The name of the earthquake is in the last column. The data for this table have been extracted from the data base of the Geophysical Institute.

In Table 2 the identification numbers of the recordings are presented. The first six columns are analogous with those of Table 1. The last column shows the identification numbers of all records (according to the disk file names in the data base). In the identification number, e.g. IIB013, II-means that the accelerogram has been corrected; B - that

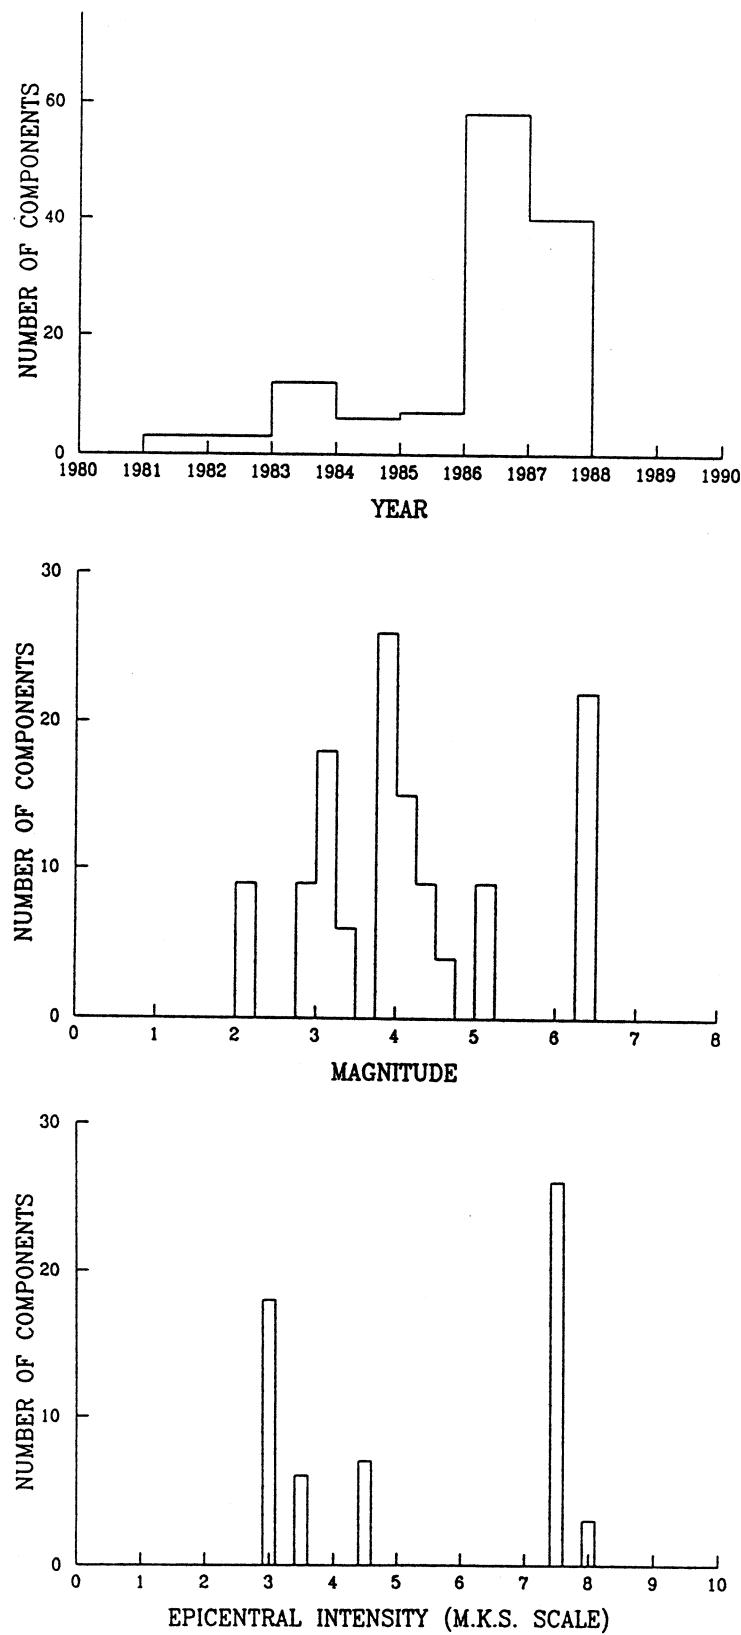

Figure 2 Distribution of recorded components by year, magnitude and epicentral intensity.

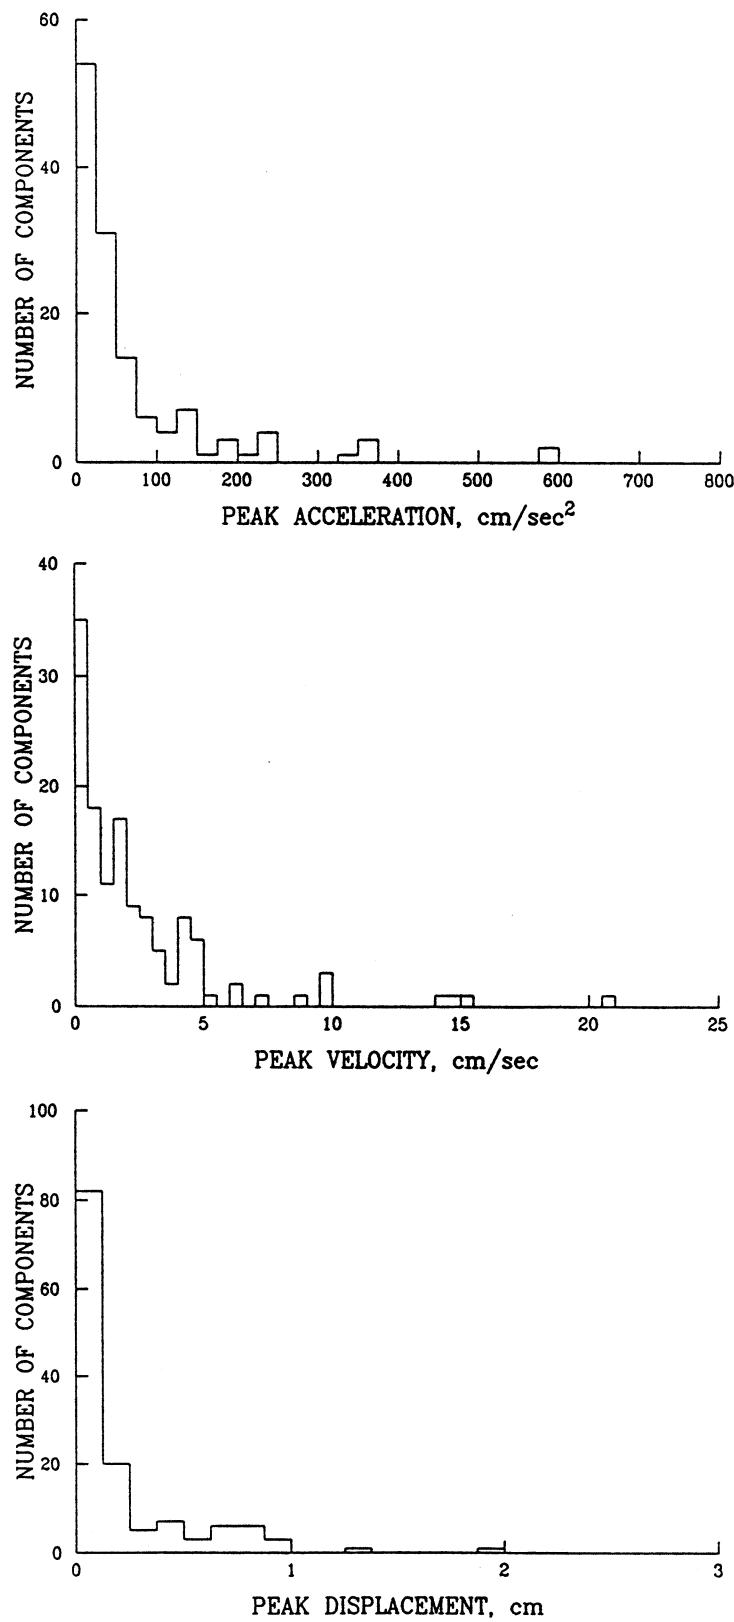

Figure 3 Distribution of recorded components by peak acceleration, peak velocity and peak displacement.

the recording has been in Bulgaria; and 13 - is the sequential number of the record in the data base.

In Table 3 the epicentral distances of the stations are shown. In the first three columns the sequential number and the name and the date of the earthquake are shown. In the fourth and the fifth columns are the identification number and the address of the station, respectively. In the last column the distances D in km from the epicenter to the stations are presented.

For a given identification or a logical file number of the record, Table 4 gives the address of the recording site. The first two digits of the logical file number, for example 87.122.3872, stand for the year of the recording. The next three digits, 122 in the above example, represent the date of the event according to the Julian calendar, and the last four digits, 3872 in this example, designate the serial number of the accelerograph.

In Table 5, the corresponding orientations of the components are given for each of the identification and the logical file numbers of the record.

Table 6 presents information on the maximum amplitude of the recorded acceleration,  $A_{max}$ , velocity,  $V_{max}$ , displacement,  $D_{max}$ , the times of their occurrence ( $t_{max}$ ) and the frequency window of the filter ( $f_1 - f_2$ ) used. The amplitudes of the acceleration are in  $\text{cm}/\text{s}^2$ , of the velocity - in  $\text{cm}/\text{s}$  and of the displacement in cm. The frequency window is in Hz and, for the frequencies in this interval, signal-to-noise ratio is greater than one (Georgiev and Paskaleva, 1987).

The main part of this report consists of figures which give graphical presentation of the records. The first figure presents the corrected acceleration. In the second figure the Fourier and the Response Spectra of the accelerograms are shown. Such a pair of figures repeats for the three components of each record. In the title data of the first figure are shown: the name, the date and the time of the earthquake, the identification numbers of the record (II means that the data has been corrected), the place where the data has been recorded, and the maximum amplitudes of acceleration. The title data of the second figure repeats most of the same information. The Fourier amplitude spectrum is drawn

with dashed lines, and the Response Spectra, for damping values 0, 2, 5, 10 and 20% of critical, are drawn with solid lines.

This first edition of the accelerograms, recorded on the territory of Bulgaria, will give the users an opportunity for efficient selection of records with specified parameters on their amplitudes and duration (Trifunac and Westermo, 1976). In future, more advanced system for data access will be available (Lee and Trifunac, 1984,1987), in form which is same as the one used in this report. The simplified graphical presentation of the data, as presented here, has proved to be most practical for quick visual access and interpretation of the data.

## ACKNOWLEDGEMENTS

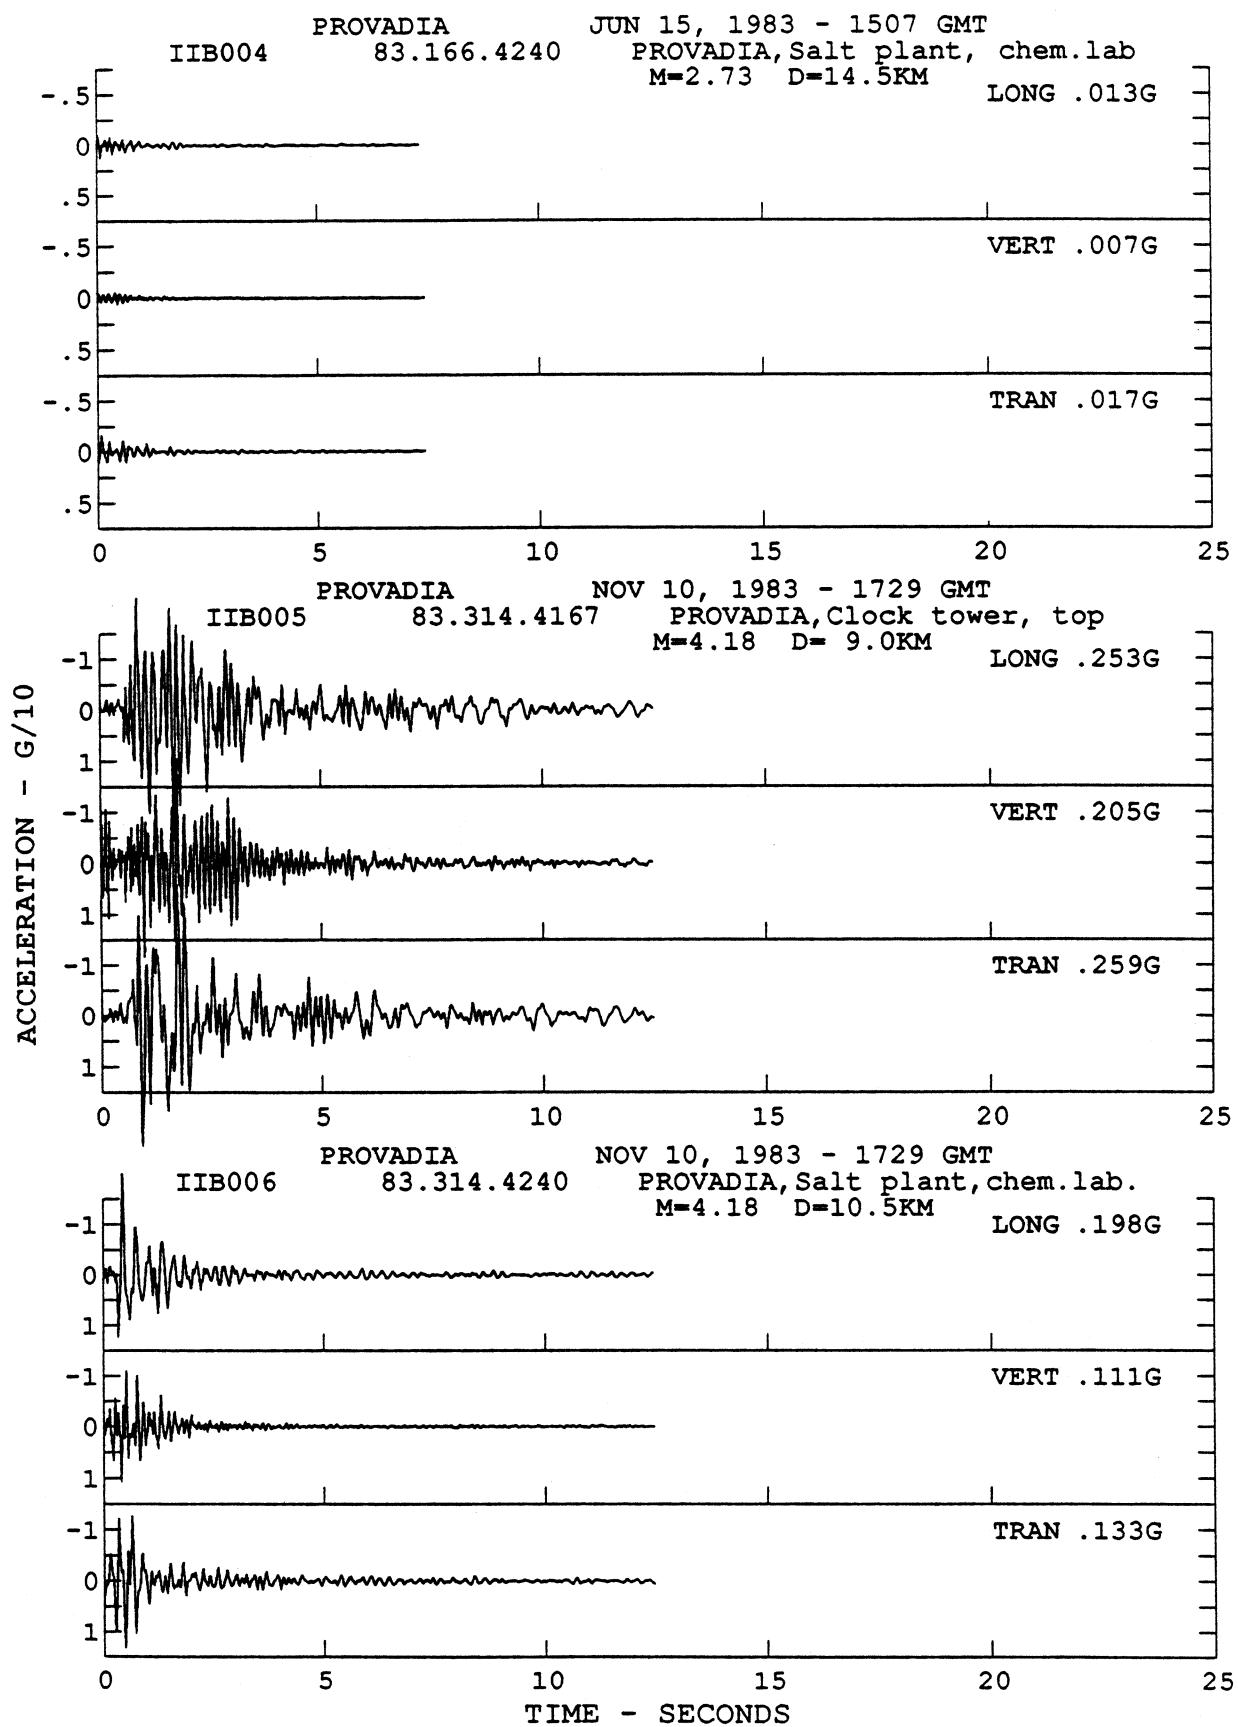

The authors of this report are indebted to the following:

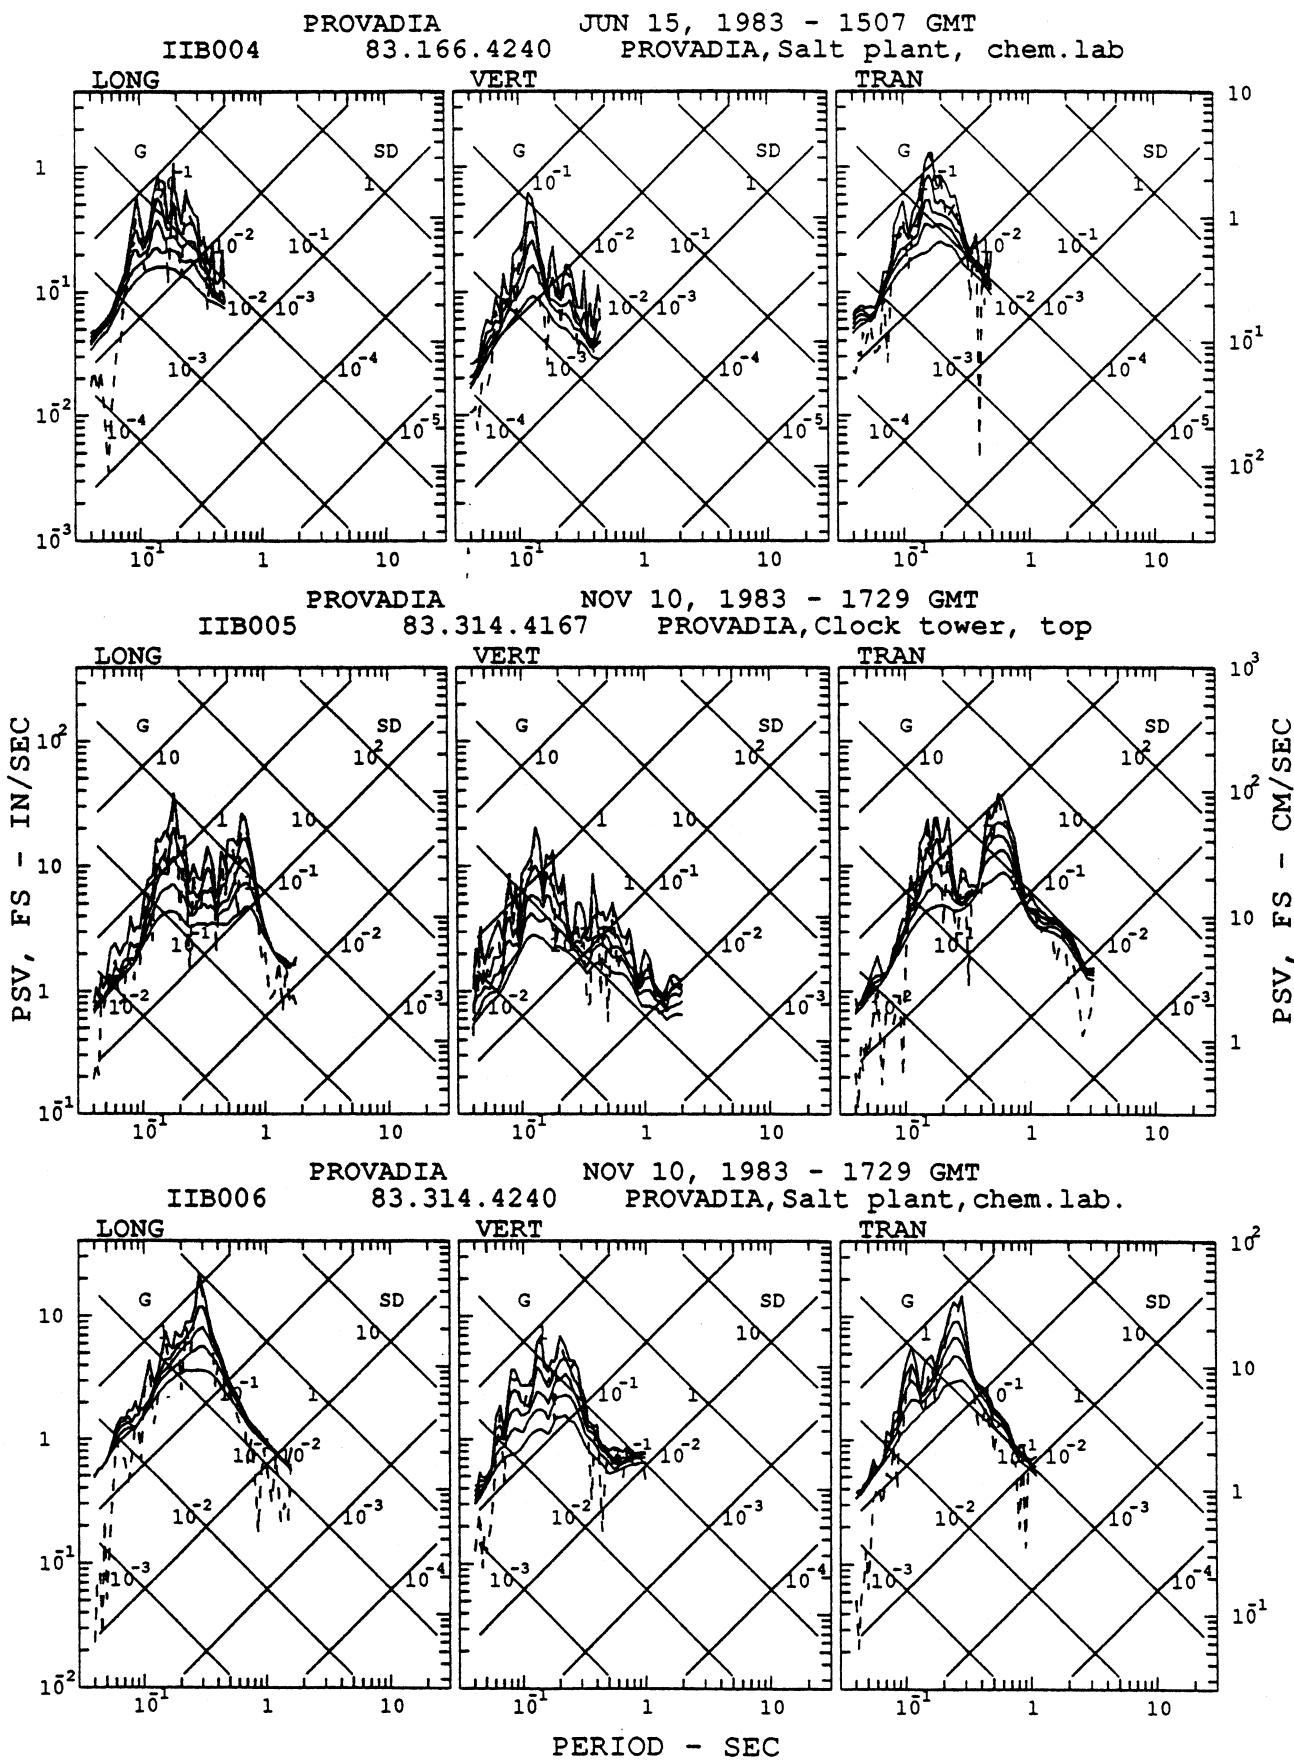

- A. Paskov and V. Ivanov, the technical team, who maintained in operating condition the entire network of earthquake recording instruments. On several occasions, they showed much enthusiasm during collection of the records, working in the earthquake epicentral regions;
- Prof. Dr. L. Hristoskov, Prof. Dr. I. Iliev, Prof. J. Karagyuleva, Dr. S. Shanov, Dr. R. Glavcheva, whose help was essential in the collection of the necessary supporting information for our report;
- Mr. I. Rumchev - for his help in the work on the software and for organizing the accelerogram data base.
- Dr. A. Tumarkin and Mr. S. Molotkov from IFZ at AN USSR - for their help in the overall concepts for building a geophysical data
